**Positional Notation**

Also called *place-value* notation

- Each place represents a power of the *base*
- Each numeral is multiplied by positional value

E.g., base 10 (decimal):

\[(4273)_{10} = 3 \times 10^0 + 7 \times 10^1 + 2 \times 10^2 + 4 \times 10^3\]

**Other Bases**

Computer scientists tend to think in powers of 2:

- Hexadecimal (base-16) – use digits 0-9, a-f (or A-F)

\[(4273)_{10} = (10b1)_{16} = 1 \times 16^0 + 11 \times 16^1 + 1 \times 16^2\]

- Octal (base-8) – mostly out of use now

\[(4273)_{10} = (10261)_{8} = 1 \times 8^0 + 6 \times 8^1 + 2 \times 8^2 + 1 \times 8^3\]

- Binary! (0s and 1s)

\[(4273)_{10} = (0001 0000 1011 0001)_{2}\]

**Bits and Bytes**

Computers work with bits – 0’s and 1’s

- (Positive) integers are represented in base 2:
  
  \[
  \begin{align*}
  0 &= 0_2, \\
  1 &= 1_2, \\
  2 &= 10_2, \\
  3 &= 11_2, \\
  4 &= 100_2, \\
  5 &= 101_2, \text{ etc.}
  \end{align*}
  \]

- Computers organize bits into bytes – 8-bit chunks

- C++ data types are organized into bytes
  - char uses 1 byte
  - int uses 4 bytes
  - double uses 8 bytes

- Get size of a variable/object type with *sizeof*:

\[\text{int sz_of_dbl} = \text{sizeof(double)};\]
**POINTERS AND MEMORY**

Computer memory is organized as an indexed array of bytes:

```
0x1000 0x1001 0x1002 0x1003 0x1004 0x1005 0x1006 0x1007 0x1008 0x1009
```

We say that the byte value 72 is stored at address 0x1004...

However, from the programmer's perspective, the value stored at 0x1004 depends on the type. It could be an int value (4 bytes)...

```
0x1000 0x1001 0x1002 0x1003 0x1004 0x1005 0x1006 0x1007 0x1008 0x1009
```

Or the start of a string...

Reference (address of) Operator &

Suppose this int value corresponds to the variable x:

```c
int x = 1819043144;
```

We can obtain the address of x using the operator &:

```c
cout << &x << endl; // prints 0x1004
```

(Try it!)

Pointers

A pointer is a variable that stores an address:

```c
int *p = &x; // p now stores 0x1004
```

The type of the variable p is int*. Note that int* is only for pointers to int; every type T has a corresponding pointer type T*.

You can write:

- int* p;
- int * p;
- the compiler interprets them all the same.
Dereference Operator *

You usually don't want to see the address itself, but what is at the address — you can get the pointed-to value by using `*`:

```c
int x = 1819043144;
int* p = &x;
cout << *p << endl;
```

The previous line outputs the same thing as:

```c
cout << x << endl;
```

So Where Do Pointers Live…?

In memory, of course!

```c
int x = 1819043144;
int* p = &x;
And yes, you can declare pointers to pointers, ad infinitum...
int** pp = &p;
int*** q = &pp;
```

Pointers As Variables

Pointers can be assigned like any other variable:

```c
int x, y;
int* p = &x; // p points to x
int* q = p; // now q and p point to x
p = &y; // now p points to y, q to x
*q = 15; // x now stores 15
```

Assigning Through *

Suppose we change the value of x:

```c
int x = 1819043144;
int* p = &x;
x = 6;
```

We can also assign through the `*` operator:

```c
*p = 17;
```

Pointers Independence

Suppose we change the value of x:

```c
int x = 1819043144;
int* p = &x;
```

x changed; p didn’t.

```c
int x = 1819043144;
int* p = &x;
```

x changed; p didn’t.

```c
int x = 1819043144;
int* p = &x;
```

x changed; p didn’t.
The nullptr Pointer

- C++ defines a special keyword for pointers which do not currently point to anything: nullptr
  int* p = nullptr;

- A null pointer is never a valid memory address:
  int* p = nullptr;
  cout << *p << endl;  // crash
  *p = 42;  // also crash

- Prior to C++ 11, the value NULL was used instead of nullptr. You will see a lot of code using NULL.

Dereferencing Pointers

- Given a pointer p to some value:
  *p dereferences p, is equivalent to the value.

- Suppose p points to an object or structure:
  (*p).foo dereferences p and accesses the member foo
  p->foo does the same thing

- In the next lecture we’ll see that array indexing is another kind of dereferencing:
  p[i] == *(p + i)
  (But we’ll have to explain pointer arithmetic first.)

Multiple Pointer Declaration

An oddity of C/C++: we must do
  int *p, *q;  // we have to use * for both even though int* is the type.

Otherwise:
  int *p, q;  // p is an int*, but q is an int
